### Introduction

This is the introduction.

#### 1.1 Motivation

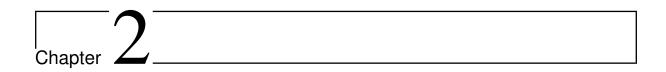

This will be the section on the motivation for the assignment.

#### 1.2 Objective

This will be the section where i outline the objective of the assignment.

#### 1.3 Structure of Thesis

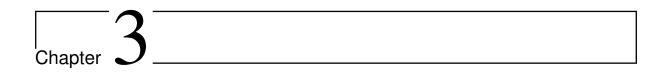

Here the outline for the rest of the assignment will be given.

## Myocardial Imaging and Echocardiography

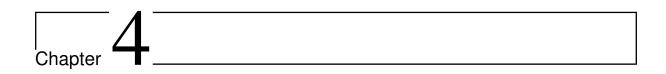

This will be a kind of theory section about echocardiography, and strain imaging.

- 2.1 Basic Cardiology
- 2.2 Introduction to Echocardiography
- 2.3 Myocardial Strain

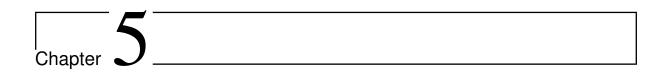

## Machine Learning Theory

This section will act as a theory section for the machine learning models used.

### Review of The Literature

This chapter will contain the review of the literature.

### Data Exploration

In this chapter the variability, distribution and type of data used in the assignment will be explored. The exploration is divided into three sections corresponding to the three main groups of variables: The patient meta-data, the input variables and the target variables. The meta-data is the data about the patients which is not used in the classification models, but can be used to give a description of the patient demographich which makes up the dataset. The input variables are the variables that are inputed into the machine learning models in order to train them, and later used to make predictions about the patients' target variables. The target variables are then variables that the models will be trained to predict. Target variables are used both in training to correct erroneus predictions that models make during training, and to evaluate the accuracy of the model after training.

#### 5.1 Patient Meta-data

The patient meta-data that will be considered in this section are age, gender, Body Mass Index (BMI) and blood pressure.

Figure 5.1 shows the patient distributions with regard to age, gender and BMI. As evident from the figure the patients that make up the dataset is made up of 138 males and 57 females. The majority of the patients are in the age group 60-80 years with a number of patients in the range 80-90 years (AGE SECTION SUBJECT TO CHANGE). The BMI distribution of patients is centered around  $26 \ kg/m^2$ . Figure 5.2 shows the joint distribution of systolic and diastolic blood pressure among the patients.

Figure 5.1: Distribution of age, gender and BMI.

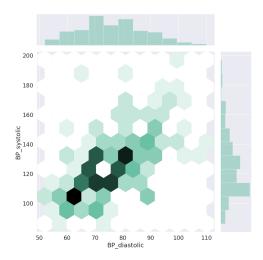

Figure 5.2: A joint distribtion plot of systolic and diastolic blood pressure of the patients.

#### 5.2 Input variables

As mentioned earlier in section REF the different machine learning models that will be applied will apply two types of input data, time-series data in the form of longitudinal strain curves, and point-values in the form of peak systolic global longitudinal strain and patient EF.

#### 5.2.1 Peak values

As mentioned in section REFERENCE EF values below 40-50% is regarded as unhealthy with regard to probability of heart failure. Keeping that in mind, one should note that the distribution of EF values among the patients shown in figure 5.3 is centered at approximately 40% with tails going as low as 8% and as high as 70%. Figure 5.4 shows the distribution of peak systolic GLS values, four the three different views. As evident from the figure, the values are centered around -12.5 with tails going as low as -29, and as high as -2.5.

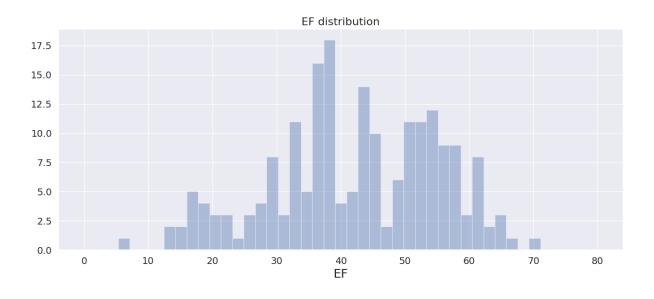

Figure 5.3: Distribution of patient EF values.

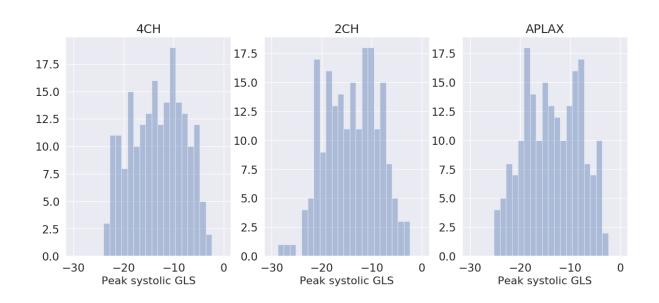

Figure 5.4: Distribution of peak systolic global longitudinal strain.

#### 5.2.2 Strain curves

Figure 5.5 shows what a typical set of strain curves look like for a patient. Only the six regional strain curves, and the one global strain curve from the 4CH view have been included as they are fairly similar across the different views. Since the data from the different patients have been taken at different times, and possibly with different ultrasound machines factors such as number of samples per strain curve, and the frame rate of the particular ultrasound machine during an examination. Each strain curve has a standardized length of one heart cycle, due to this different curves have different number of samples. Figure 5.6 shows the distribution of frame rates, and number of samples among the total number of strain curves.

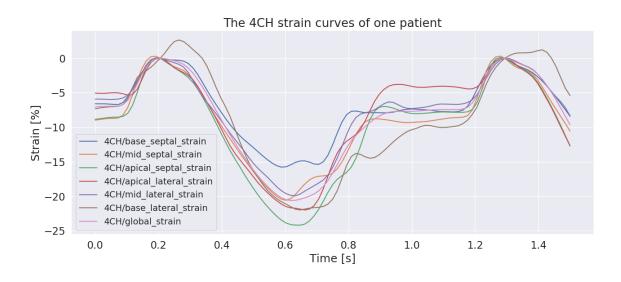

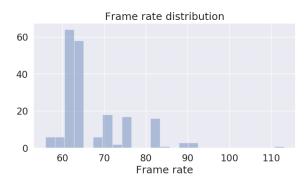

Figure 5.5: Plot of the global and regional longitudinal strain curves of one patient in the 4CH view.

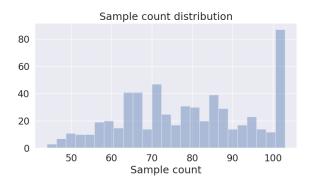

Figure 5.6: Distribution of the frame rate used in the ultrasound imaging used to obtain the strain curves (left), and sample count of the different strain curves (right).

#### 5.3 Target variables

Figure 5.7 shows the distribution of heart failure among patients (left), and the distribution of different indications (right). Since the dataset has approximately as many patients with a heart failure diagnosis as without, it can be considered balanced in that regard. With regard to the different patient diagnosises, their rate of occurance can is not uniform in this dataset. The control group of healthy individuals consists of 31 patients. The groups of patients with STEMI, and NSTEMI indications consist of 60 and 39 patients respectively. Finally, the group of patients with heart failure, but with a non-stemic indication (labelled OTHER in left barplot in figure 5.7) consists of 69 patients.

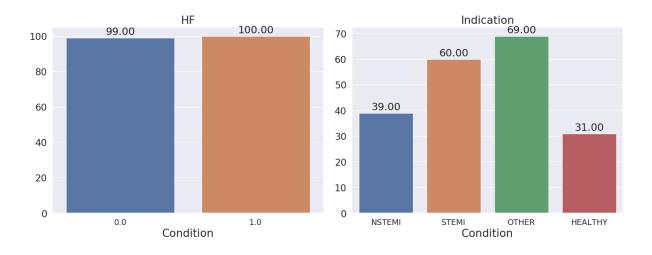

Figure 5.7: The distribution of heart failure and different indications within patients.

To illustrate the diagnostic power of EF, and peak strain values figure 5.8 shows the distribution of EF for patients with and without heart failure (left), and the distribution of EF for patients in the control group and the other patients (right). Figure 5.9 shows the distribution of peak systolic GLS values for patients with and without heart failure, and figure 5.10 shows the distribution of peak systolic GLS values for patients in the control group and the rest of the patients. From the samples used to produce the left plot in figure 5.8 and figure 5.9 it seems as though the heart failure patients are more separable with the EF values than with the GLS values. With regard to separability of patients with diagnoses and patients in the control group it seems as though the right plot in figure 5.8, and figure 5.10 follows the same distribution as

the heart failure patients. However, it is hard to make an evaluation on this since the sample size of the control group is much smaller than the group of diagnosed patients.

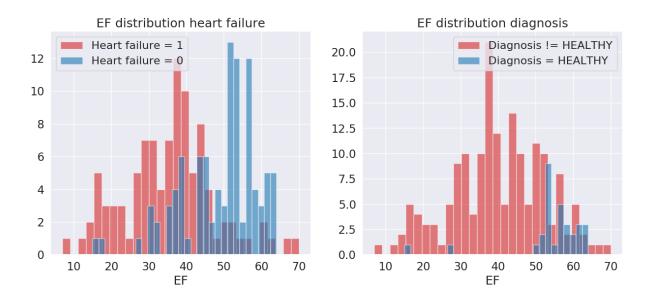

Figure 5.8: Distribution of EF for patients with and without heart failure (left), and distribution of EF for patients in the control group, and patients with a diagnosis.

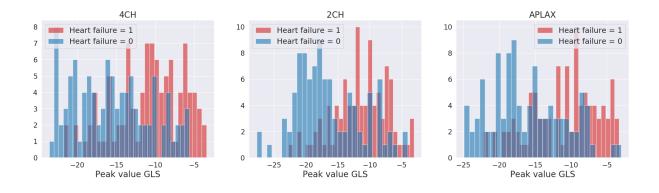

Figure 5.9: Distribution of GLS for patients with and without heart failure.

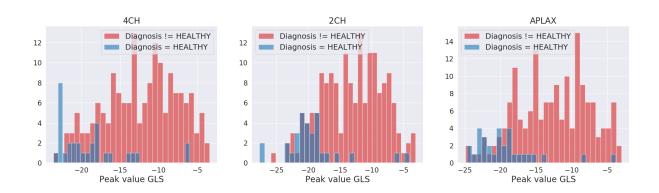

Figure 5.10: Distribution of GLS for patients in the healthy control group, and the other patients.

Figure 5.11 shows the distribution of the different segment indications, for all the left ventricle segments of all the patients in the dataset. Since the occurance of indications other that "normal" and "hypokinetic" are very rare, the occurance axis has been used as logarithmic. The imbalance of segment-indication labels illustrated in figure 5.11 means that it will challenging for any statistical model to perform well in the classes with low occurance. To counteract this one can change the taxonomy of the labels such that the classification problem becomes binary with the labels Normal and Not normal. The dataset is then fairly evenly distributed with 1695 Normal labels and 1818 Not normal labels.

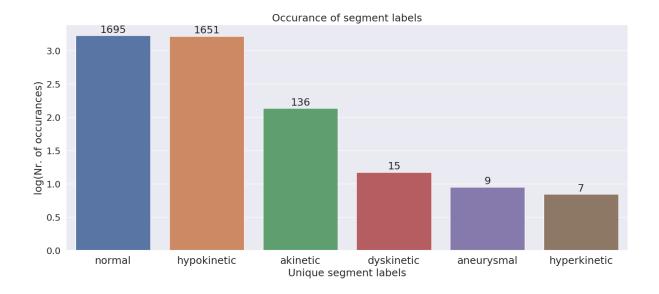

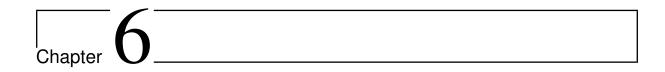

Figure 5.11: Distribution segment indication labels.

### Method

#### 6.1 Models

This is the section where we detail the specific models used.

- 6.1.1 Time-series clustering
- 6.1.2 Peak-value clustering
- 6.1.3 Recurrent Neural Network
- 6.1.4 Supervised Peak-value Classifiers

#### 6.2 Description of The Datasets

Since the different ML models detailed in chapter REFERENCE require different types of input data the, datasets have been divided into two main categories: The peak-value datasets and the time-series datasets.

#### 6.2.1 Time-series Datasets

Nr	Input variables	Shape
1	Single RLS curves	(3600, 1)
2	RLS curves	(200, 18)
3	GLS curves	(200, 3)
4	Strain curves	(200, 21)

Table 6.1: Time-series datasets. The "Shape" parameter is indicates: (Number of objects in the dataset, Number of curves used to represent each individual object). The curve length is not included in the shape parameter because it differs for different curves.

Table 6.1 shows the different time-series datasets that will be used. All the datasets except *Single RLS curves* will be used to predict whether or not the patient is diagnosed, and whether the patient has heart failure. Recall that the different diagnosises are described in section REFER-ENCE, and there occurance rate are illustrated in figure 5.7. *Single RLS curves* will be used to

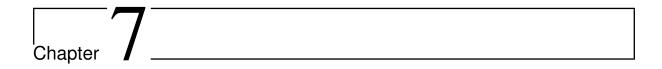

predict the segment indications shown in figure ?? and described in section REFERENCE. The point of classifying individual segments of a patients left ventricle is that if a single segment is found to be *not normal*, this would also mean that the patient can be considered as *not healthy*. As mentioned in the description of table 6.1 the "Shape" parameter shows how many objects each dataset has, and how many curves are associated to each object. Since each ultrasound examination takes ultrasound inspections from three views (four chamber, two chamber, and APLAX chamber), each patient has three views to estimate a GLS curve from. Since each GLS curve, also can be divided into six RLS curves, there is a total of 21 strain curves per patient. Since each patient has 18 RLS curves, there are  $18 \times 200 = 3600$  curves that make up dataset number 1. Both the RNN, and the TSC model are applied on the datasets listed in table 6.1,

#### 6.2.2 Peak-value Datasets

Nr	Input variables	Shape
1	Single peak systolic RLS values	(3600, 1)
2	Peak systolic RLS values	(200, 18)
3	Peak systolic GLS values	(200, 3)
4	Peak systolic strain values	(200, 21)
5	Peak systolic RLS, and EF values	(200, 19)
6	Peak systolic GLS, and EF values	(200, 4)
7	Peak systolic strain, and EF values	(200, 22)

Table 6.2: Peak-value datasets. The "Shape" parameter is indicates: (Number of objects in the dataset, Number of dimensions used to represent each individual object).

Table 6.2 shows the different peak-value datasets. All the datasets with exception of Single peak systolic RLS values will be used to predict the diagnosis of patients, and whether the patient has heart failure. Single peak systolic RLS values is also the only peak-value dataset that is not suited for clustering, since a minimum of two dimensions is required to cluster a point-value dataset. The reason that there are more peak-value datasets than there are time-series datasets, is that the peak-value version of three datasets in table 6.1 have been combined with EF to determine whether a combination of peak systolic strain, and EF can have a higher predictive power than strain alone.

### Results

In this chapter the results will be presented in the form of three case studies. Each case study will focus on a single target variable, and aims to find which model group performs best at predicting the target variable in question. Recall that the three target variables that will be considered in this thesis are: Heart failure, patient diagnosis, and the indication of individual left ventricle segments. As mentioned earlier in the chapter, four model groups will be tested. The case studies will first deal with each model group individually, where variants of the models with different hypermarameters will be tested on the different datasets. Then, the best performing model within each model group will be used to compare the four model groups. The supervised models will be assessed with the metrics: accuracy, sensitivity, specificity and DOR. The clustering methods evaluated at two cluster centers will be assessed with the same methods as the supervised models. The clustering methods evaluated at two to nine cluster centers will also be assessed with ARI to determine whether the models evaluated at a higher number of cluster centers could fit the data better.

#### 7.1 Case Study: Heart Failure

#### 7.1.1 Time-series Clustering

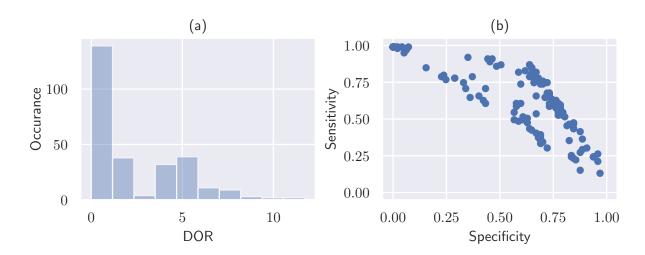

Figure 7.1: (a) Distribution plot of DOR of all TSC methods evaluated at two cluster centers when applied to classify heart failure. (b) Scatter plot of the same methods sensitivity, and specificity.

Dataset-Method	Accuracy	Sensitivity	Specificity	DOR
gls/2CH/regular/centroid/2	0.76	0.87	0.64	11.72
${\rm gls/2CH/scaled/centroid/2}$	0.76	0.87	0.64	11.72
${\rm gls/2CH/regular/average/2}$	0.75	0.85	0.65	10.38
${\rm gls/2CH/scaled/average/2}$	0.75	0.85	0.65	10.38
${\it gls-rls/2CH/scaled/ward/2}$	0.74	0.82	0.67	9.14

Table 7.1: The accuracy, DOR, sensitivity and specicity scores of the five best performing two-cluster-center TSC methods in terms of DOR, at detecting heart failure. The **Dataset-Method** column indicates Dataset used/View used/Type of preprocessing used/Linkage criteria of method/Number of cluster centers.

Figure 7.1a shows that the DOR is close to zero for many of the two-cluster-center methods, However, the best performing methods are able to acheive a DOR above ten, these methods are listed in table 7.1. From the scatterplot in figure 7.1b one can see that the distribution of sensitivity, and specificity are quite widespread. Sensitivity and specificity scores range from 0 to 1. Common to the top 18 methods in terms of DOR is that they all use data from a single view, and 2CH is the only view that is represented among the five methods with highest DOR. What else is worth noting is that almost all the methods using normalization or z-normalization as preprocessing score below the methods that use scaling, or no preprocessing at all. These observations can be confirmed from the table10.1 in the appendix. From table 7.1 one can see that the two best-performing methods in terms of DOR received the exact same score in all metrics. gls/2CH/regular/centroid/2, and gls/2CH/scaled/centroid/2 differ only in the way of preprocessing, the former does not preprocess the curves before clustering, and the latter uses scaling. However, for these two cases preprocessing did not matter as they have the exact same cluster assignments as well.

Dataset-Method	ARI
gls/2CH/regular/centroid/2	0.25
${\rm gls/2CH/scaled/centroid/2}$	0.25
${\rm gls/2CH/scaled/centroid/3}$	0.24
${\rm gls/2CH/regular/centroid/3}$	0.24
${\rm gls/2CH/scaled/average/2}$	0.24

Table 7.2: The five highest ARI scores attained when applying TSC for detecting heart failure. The **Dataset-Method** column indicates Dataset used/View used/Linkage criteria of method/Number of cluster centers.

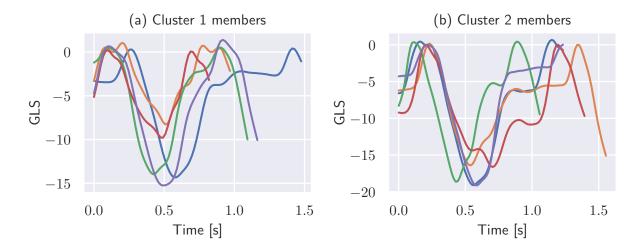

Figure 7.2: Here the curves of five random cluster members assigned by the gls/2CH/regular/centroid/2 method. Each plot depicts the 2CH GLS curves for five random cluster members from the gls/2CH/regular/centroid/2 method. (a) and (b) contain members from cluster 1 and 2 respectively. Only five curves are included to avoid making the plot to chaotic.

The majority of ARI scores are close to zero, but 17 methods evaluated at different numbers of cluster centers are able to acheive an ARI score above 0.20. As with DOR, the general trends for methods with a high ARI score is that they use data from a single view, use scaling or no preprocessing at all. From table 7.2 one can see that the top five methods only use the GLS curve from the 2CH view. In addition, one can also see that the two methods with the highest ARI (0.25) are the clustering methods evaluated at two cluster centers that perform best in terms of DOR as well. This means that there most likely are no methods evaluated at a number of cluster centers higher than two that will perform better than qls/2CH/regular/centroid/2, or qls/2CH/scaled/centroid/2. Figure 7.2 shows the 2CH GLS curves of five random cluster members from the qls/2CH/regular/centroid/2 method. Although one cannot make any conclusive statements about what the general similarities between cluster members are, from the plots in figure 7.2 it seems like the curves of cluster 2 are smooth, while the curves of cluster 1 are more irregular in shape, which makes sense as this clustering algorithm uses a shapebased distance measure. Since gls/2CH/regular/centroid/2 is one of two methods to acheive the highest DOR (11.72), accuracy (0.76), and ARI (0.25) it is chosen as the best of the TSC methods at identifying heart failure among patients. gls/2CH/regular/centroid/2 is chosen over gls/2CH/scaled/centroid/2 because it does not require preprocessing.

#### 7.1.2 Peak-value Clustering

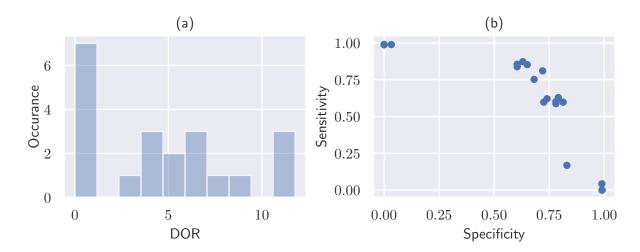

Figure 7.3: (a) Distribution plot of DOR of all PVC methods evaluated at two cluster centers when applied to classify heart failure. (b) Scatter plot of the same methods sensitivity, and specificity.

From figure 7.3a one can see that the majority of DOR scores are centered around zero, but there is a substantial number of methods that acheive a DOR score above 10. The scatterplot in figure 7.3b shows that there is also a great spread in sensitivity, and specificity. A few methods are spread along the edges of the plot acheiving a sensitivity or specificity score close to zero, but there are also methods that aceive sensitivity and specificity scores above 0.7. Common to the highest performing PVC methods is that they all use the dataset that is a combination of peak systolic GLS values and EF values. This can be confirmed from the complete table of results in the appendix 10.4. From table 7.3 one can see that gls-EF/ward/2 is the PVC method that acheives the highest DOR of 11.59 when applied to classify heart failure. The gls-EF/complete/2 method acheives the second highest DOR of 10.85, but its' specificity is nine points higher than gls-EF/ward/2, while its sensitivity is only six points lower, and it also has the highest accuracy of all the PVC methods applied to identify heart failure.

Dataset-Method	Accuracy	Sensitivity	Specificity	DOR
gls-EF/ward/2	0.75	0.87	0.63	11.59
${\it gls-EF/complete/2}$	0.76	0.81	0.72	10.85
${\it gls-EF/average/2}$	0.75	0.85	0.65	10.58
rls-EF/complete/2	0.73	0.86	0.60	8.89
gls-rls-EF/ward/2	0.72	0.84	0.60	7.80

Table 7.3: The accuracy, DOR, sensitivity and specicity scores of the five best performing twocluster-center PVC methods in terms of DOR, at detecting heart failure. The **Dataset-Method** column indicates *Dataset used/Linkage criteria of method/Number of cluster centers*.

Dataset-Method	ARI
gls-EF/complete/2	0.27
$\operatorname{gls-EF/ward/2}$	0.24
${\it gls-EF/average/2}$	0.24
rls-EF/complete/2	0.21
gls-EF/complete/3	0.21

Table 7.4: The five highest ARI scores attained when applying PVC for detecting heart failure. The **Dataset-Method** column indicates *Dataset used/Linkage criteria of method/Number of cluster centers*.

Many of the ARI of PVC methods for classifying heart failure are close to zero, but substantially more of the methods score above zero in ARI As with DOR, the methods that acheive the highest ARI scores use datasets that are combinations of strain curves and EF values. Table 7.4 shows that the three highest ARIs are attained by the same three methods that acheived the highest DORs. This means that there are most likely no methods evaluated at a higher number of cluster centers that will outperform ward/2, or complete/2 at classifying heart failure. However, complete/2 acheives the highest ARI, although it only acheives the second highest DOR. complete/2 is chosen as the best performing PVC method when classifying heart failure, since it has the highest accuracy (76%), highest ARI (0.27), and second highest DOR (10.85). In figure 7.4 scatterplots patients are plotted with the dimensions: 4-chamber peak systolic GLS, 2-chamber peak systolic GLS and EF. The colors of the points correspond to wheather the patient has heart failure or not, and which cluster the points belong to. The plots are actually a lower dimensional projection of the GLS-EF peak-value dataset. This particular projection was chosen as it was found to be the projection where heart failure patients were as separable as possible. From plots 7.4b-d one can see that the clusters are fairly separable, heart failure on the other hand is not as easy to separate in these dimensions as can be seen in plot 7.4d. Ward/2 and complete/2 can in some sense be considered as binary classifiers where values under a certain threshold are categorized as heart failure. The ward/2 method has the highest threshold for what is considered heart failure, and complete/2 has the lowest, which explains their difference in sensitivity and specificity score. Since method complete/2 acheives the highest accuracy (0.76), highest ARI (0.27) and second highest DOR (10.85) it is chosen as the best PVC method to identify heart failure among patients.

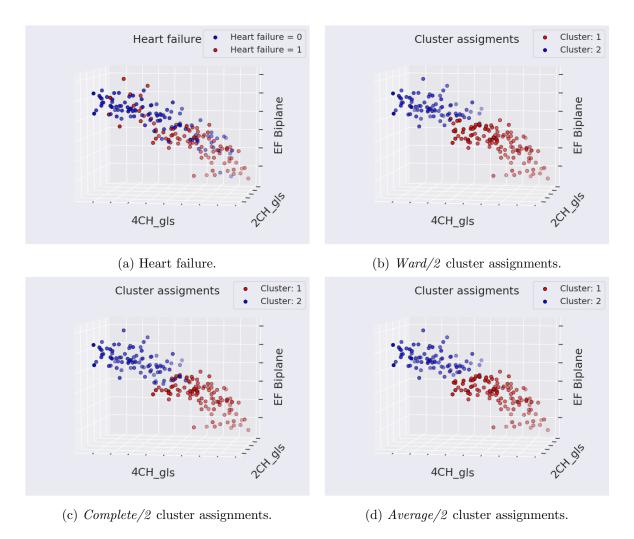

Figure 7.4: Scatterplot of peak GLS values in each view. Colors in the of the different dots are given by heart failure diagnosis, and cluster assignments of ward/2, complete/2 and average/2 methods. Numbers are not included on the axes because the point of the figure is to illustrate the separability of clusters, and heart failure.

Dataset-Model	Accuracy	Sensitivity	Specificity	DOR
gls/4CH/upsampled	0.54	0.46	0.61	1.36
rls/APLAX/regular	0.53	0.48	0.58	1.30
rls/4CH/regular	0.52	0.36	0.68	1.20
${\rm gls/APLAX/downsampled}$	0.52	0.63	0.40	1.15
${\rm gls/2CH/downsampled}$	0.51	0.61	0.40	1.03

Table 7.5: The accuracy, DOR, sensitivity and specicity scores of the five best performing variations of the NN in terms of DOR, at detecting heart failure. The **Dataset-Model** column indicates Dataset used/View used/Whether curve has been upsampled, downsampled or is regular.

#### 7.1.3 Deep Neural Network

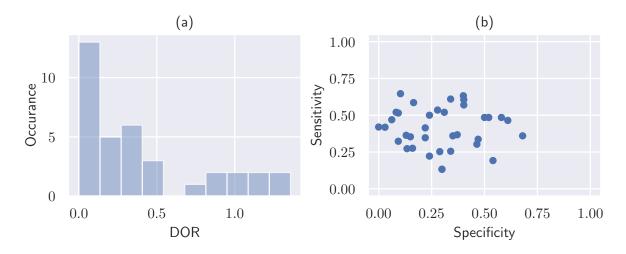

Figure 7.5: (a) Distribution plot of DOR of all NN models evaluated at two cluster centers when trained to predict heart failure. (b) Scatter plot of the same models sensitivity, and specificity.

From the distribution plot in figure 7.5a one can see that the most frequent DOR by NN models when training them to predict heart failure is zero . The highest DOR of 1.36 is attained by using only the GLS curve from the 4CH view as input, as can be seen from table 7.12. In the scatterplot in figure 7.5b one can see that sensitivity scores vary between 0.15 and 0.65, and the specificity scores vary between 0 and 0.68. The majority of the NN variations acheive a sensitivity, specificity and accuracy below 0.50. The accuracy of the model variations are also fairly low, 0.54 being the highest accuracy acheived. Since the heart failure dataset is fairly evenly distribution (recall figure 5.7) an accuracy of 0.54 is not much better than what could be acheived by randomly guessing the label. The 11 highest DORs attained by NN models trained to classify heart failure are acheived using only curves from single views as input, and only GLS, or RLS curves. Gls/4CH/upsampled will be considered the best model variation of the NNs at predicting heart failure since it acheives the highest accuracy and DOR .

Dataset-Model	Accuracy	Sensitivity	Specificity	DOR
gls-EF/Gaussian-Process	0.75	0.78	0.73	9.40
rls- $EF/MLP$	0.75	0.76	0.74	9.37
rls- $EF/Linear$ - $SVM$	0.75	0.75	0.74	8.86
gls-EF/Ada-Boost	0.75	0.77	0.73	8.85
gls-EF/Naive-Bayes	0.75	0.76	0.74	8.79

Table 7.6: The accuracy, DOR, sensitivity and specicity scores of the five best performing PVSC in terms of DOR, at detecting heart failure. The **Dataset-Model** column indicates *Dataset used/The specific ML model used*.

#### 7.1.4 Peak-value Supervised Classifiers

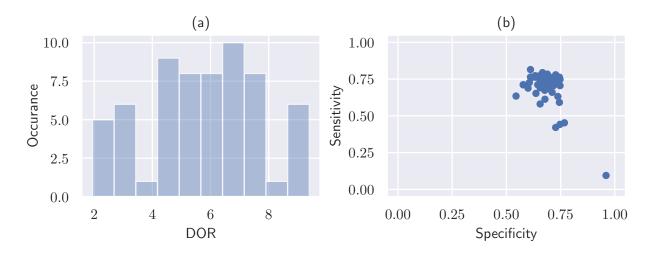

Figure 7.6: (a) Distribution plot of DOR of all PVSC models evaluated at two cluster centers when trained to predict heart failure. (b) Scatter plot of the same models sensitivity, and specificity.

From the distribution plot depicted in figure 7.6a one can see that the PVSC models overall acheive relatively high DORs, with a range of approximately two to nine. The scatterplot in figure 7.6b shows that the models are quite concentrated in terms of sensitivity and specificity scores. The majority of the models achieve sensitivity, and specificity scores in the ranges 0.6 to 0.75, with some outliers acheiving specificity below 0.5 and sensitivity above 0.75. What is even more concentrated are the accuracy scores of the models. As can be seen in table 7.6, the accuracy of top five PVSC models are all 0.75 As with PVC all the best performing PVSC models use a combination of EF and peak systolic strain values, and no specific ML model seems to outperform the others on all the datasets in term of DOR. The table also shows that the highest DOR of 9.4 is acheived by model gls-EF/Gaissian-Process. Although the DOR, sensitivity and specificity scores are very similar for the five best performing models gls-EF/Gaussian-Process is chosen as the PVSC model that performs best at predicting heart failure as it acheives the highest DOR.

Dataset-Model	Accuracy	Sensitivity	Specificity	DOR
TSC-gls/2CH/regular/centroid/2	0.76	0.87	0.64	11.72
${f PVC}$ -gls-EF/complete/2	0.76	0.81	0.72	10.85
$\mathbf{NN}$ -gls/4CH/upsampled	0.54	0.46	0.61	1.36
${\bf PVSC}\text{-}{\bf gls}\text{-}{\bf EF}/{\bf Gaussian}\text{-}{\bf Process}$	0.75	0.78	0.73	9.40
Dataset-Model	TP	TN	FP	FN
TSC-gls/2CH/regular/centroid/2	86	62	35	13
${f PVC}$ -gls-EF/complete/2	77	72	28	18
$\mathbf{NN}$ -gls/4CH/upsampled	46	61	39	53
PVSC-gls-EF/Gaussian-Process	74	72	27	21

Table 7.7: A table comparing the best contenders within each model group for predicting heart failure among patients. The top table comprare the models by their accuracy, sensitivity, specificity and DOR, and the bottom table shows the number of TPs, TNs, FPs and FNs that the different models attain.

#### 7.1.5 Comparisons

With exeption of the NN, the models performance of the different models are very close in terms of DOR and accuracy. From table 7.7 one can see that the TSC method gls/2CH/regular/centroid/2 achieves the highest sensitivity of all the models applied to predict heart failure, but it achieves the second lowest specificity of the four model groups. This can be confirmed by the fact that it attains 86 TPs, and 35 FPs. The PVSC model gls-EF/Gaussian-Process attains the most balanced score in terms of sensitivity and specificity, and the highest specificity score of all the model groups. However, the PVC model gls-EF/complete/2 attains a higher accuracy, sensitivity and DOR than the PVSC model. One can also see that the PVC model attains more TP, the same number of TN, fewer FP and fewer FN than the PVSC model. It should also be noted that the PVC model and the PVSC model are using the same dataset which is a combination of peak systolic GLS values, and EF. To conclude this particular case study, the PVC model is picked as the best model at predicting heart failure among patients as it achieves the highest accuracy of the model groups, highest number of TN, and one of the most balanced combinations of sensitivity, and specificity.

Dataset-Method	Accuracy	Sensitivity	Specificity	DOR
gls/2CH/regular/centroid/2	0.74	0.71	0.93	33.47
${\rm gls/2CH/scaled/centroid/2}$	0.74	0.71	0.93	33.47
${\rm gls/2CH/scaled/average/2}$	0.73	0.69	0.93	30.71
${\rm gls/2CH/regular/average/2}$	0.73	0.69	0.93	30.71
${\rm gls/2CH/scaled/ward/2}$	0.71	0.67	0.93	27.49

Table 7.8: The accuracy, DOR, sensitivity and specicity scores of the five best performing twocluster-center TSC methods in terms of DOR, at detecting patient diagnoses. The **Dataset-Method** column indicates Dataset used/View used/Type of preprocessing used/Linkage criteria of method/Number of cluster centers.

#### 7.2 Case Study: Patient Diagnosis

#### 7.2.1 Time-series Clustering

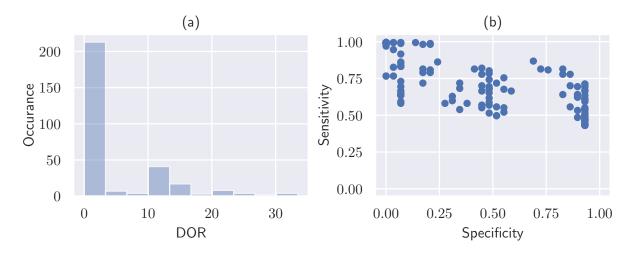

Figure 7.7: (a) Distribution plot of DOR of all TSC methods evaluated at two cluster centers when applied to classify patient diagnosis. (b) Scatter plot of the same methods sensitivity, and specificity.

From the distribution plot in figure 7.7a one can see that the majority of DORs are close to zero, but there are some methods that acheive a DOR above 30. In the scatter plot in figure 7.7b one can see that the specificity of the methods and range from 0.5 to 1, and the sensitivity scores range from 0 to 0.93. As with heart failure, the TSC methods that perform best in terms of DOR use data from a single view. The 2CH view, and GLS curves are the only view and curve that are used among the methods that achieve the five highest DORs. From the table of all the method results in the appendix 10.2 one can see that the highest performing method in terms of DOR to use a dataset other than GLS curves alone is gls-rls/2CH/scaled/ward/2 and it achieves a DOR of 26.76. One can also note that the highest performing method in terms of DOR that uses a view other than only 2CH is rls/all-views/normalized/weighted/2 which achieves a DOR of 25.56. The TSC methods that achieve the highest DOR scores all use no preprocessing, or scaling. From table 7.8 one can see that the TSC methods that achieve the highest DOR scores are gls/2CH/regular/centroid/2, and gls/2CH/scaled/centroid/2 which are the same two methods that achieve the highest DORs in the heart failure case study.

Dataset-Method	ARI
gls-rls/4CH/regular/complete/2	0.36
gls/all-views/regular/weighted/2	0.34
${\rm gls/all\text{-}views/scaled/weighted/4}$	0.33
${\rm gls/all\text{-}views/scaled/weighted/3}$	0.33
${\rm gls/APLAX/regular/single/10}$	0.32

Table 7.9: The five highest ARI scores attained when applying TSC for detecting patient diagnoses. The **Dataset-Method** column indicates *Dataset used/View used/Linkage criteria* of method/Number of cluster centers.

The majority of the ARI scorer for all the TSC methods evaluated at two to nine cluster centers are centered around zero. As with the TSC methods attaining the highest DORs the methods using no preprocessing or scaling acheive the highest ARI indices when used to identify patient diagnoses. In addition, the GLS curves are also most often part of the dataset for the TSC methods receiving the highest ARI when used to identify patient diagnoses. From table 7.9 one can see that the TSC methods receiving the five highest ARI scores, are not among the TSC methods that receive the highest DOR scores. The TSC method qls-rls/4CH/regular/complete/2 attains the highest ARI score when applied to identify patient diagnoses, and achieves an accuracy of 0.84, a sensitivity of 0.87 a specificity of 0.69 and a DOR 14.65. The TSC method qls/all-views/regular/weighted/2 achieves the second highest ARI when applied to identify patient diagnoses, and achieves an accuracy of 0.82, a sensitivity of 0.81 a specificity of 0.83 and a DOR 21.06. What should also be noted is that the TSC methods achieving the two highest ARIs when applied to identify patient diagnoses are methods evaluated at two cluster centers, which means that none of the TSC methods evaluated at cluster centers between three and nine can perform better than the ones evaluated at two cluster centers. It may seem strange that the ordered lists of DORs, and ARIs are so different. The reason for this is not because DOR inherently values sensitivity higher than specificity, but stems from how the DOR is defined. Recall that  $DOR = (TP \times TN)/(FP \times FN)$ , since the patient diagnoses dataset is skewed in favour of positives TP has the potential of being as high as 170 while TN can be as high as 30. Therefore the DOR will be higher for methods with a high sensitivity than for methods with an equally high sensitivity. In figure 7.8 curves of five random cluster members assigned by the qls/all-views/regular/weighted/2 method are plotted. As with the observations made with regard to figure 7.2 it is not possible to make any conclusive statements as to what the similarities are based on such a small sample size. However, based on the small sample size in 7.8 it seems as though the curves in cluster 2 (column (b)) are smoother in shape, than the curves in cluster 1 (column (a)). The TSC method that is chosen as the best method for identifying patient diagnoses is qls/all-views/regular/weighted/2, because it achieves the second highest ARI, and because it's sensitivity and specificity are more balanced than the method attaining the highest ARI and the methods that achieve higher DORs.

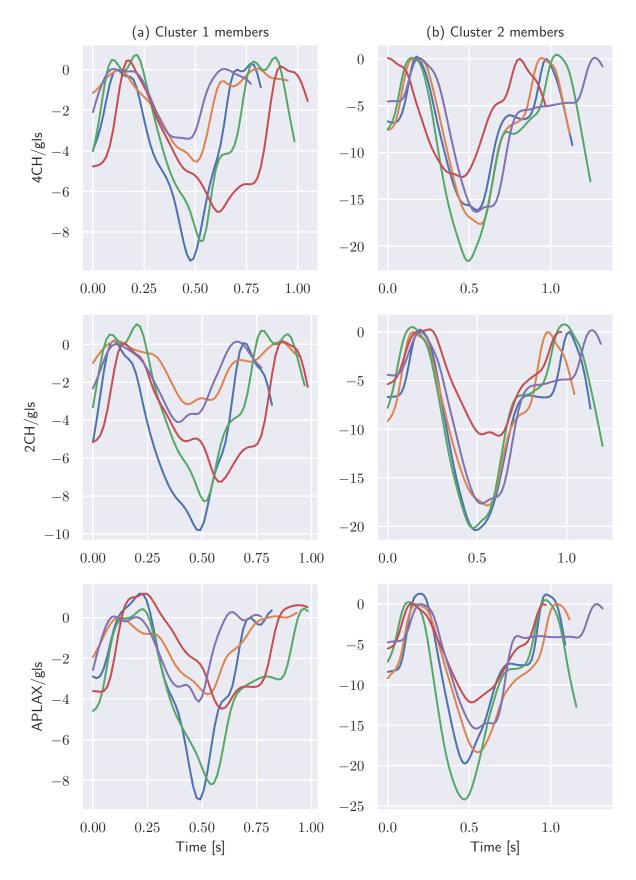

Figure 7.8: Here the curves of five random cluster members assigned by the <code>gls/all-views/regular/weighted/2</code> method are plotted. Each row represents one of the seven possible strain curves in the 4CH view. Coloumn (a) and (b) represent cluster 1 and 2 respectively. To make it easier to visually separate the curves, only five random members from cluster 1 and 2 are included in the figure.

Dataset-Method	Accuracy	Sensitivity	Specificity	DOR
gls-EF/ward/2	0.76	0.72	0.94	39.33
rls-EF/complete/2	0.77	0.74	0.93	37.61
gls-rls-EF/ward/2	0.76	0.72	0.93	35.16
${\it gls-EF/average/2}$	0.74	0.70	0.94	34.90
${\it gls-EF/complete/2}$	0.68	0.63	0.94	25.75

Table 7.10: The accuracy, DOR, sensitivity and specicity scores of the five best performing twocluster-center PVC methods in terms of DOR, at detecting patient diagnoses. The **Dataset-Method** column indicates *Dataset used/Linkage criteria of method/Number of cluster centers*.

#### 7.2.2 Peak-value Clustering

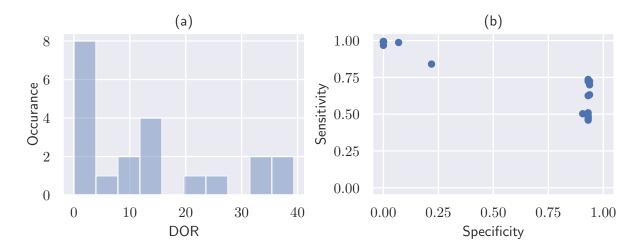

Figure 7.9: (a) Distribution plot of DOR of all PVC methods evaluated at two cluster centers when applied to classify patient diagnosis. (b) Scatter plot of the same methods sensitivity, and specificity.

From the distribution plot in figure 7.9a one can see that the majority of the PVC methods get DORs close to zero, but there are a few methods that attain DORs above 30, and close to 40. From the scatter plot in 7.9b one can see that almost all the sensitivity scores are above 0.5, while the specificity scores are concentrated in the areas 0 to 0.25 and 0.95. As with the heart failure case study the PVC methods that perform high in terms of DOR use a dataset that is a combination of peak systolic strain values and EF. From table 7.10 one can see that gls-EF/ward/2 and rls-EF/complete/2 are the two top performers in terms of DOR. gls-EF/ward/2 achieves a slightly higher specificity score, where as rls-EF/complete/2 attains a slightly higher specificity score.

The majority of the ARI scores of PVC methods applied to identify patient diagnoses are centered around zero, but as one can see from table 7.11 there are a few methods that acieve an ARI above 0.2 close to 0.3. For a change, the PVC methods that perform best in terms of ARI, are neither methods evaluated at two cluster centers, or methods that are applied on a combination of peak systolic strain values and EF. In contrast to the heart failure case study, the PVC methods that achieve the highest ARIs, when applied to identify patient diagnoses, are not the same methods that achieve the highest DORs. The two PVC methods that achieve the highest ARIs are the gls/average method evaluated at 6 and 7 cluster centers respectively.

Dataset-Method	ARI
gls/average/6	0.29
gls/average/7	0.29
gls-rls/complete/3	0.28
rls-EF/complete/2	0.26
gls-EF/ward/2	0.25

Table 7.11: The five highest ARI scores attained when applying PVC for detecting patient diagnoses. The **Dataset-Method** column indicates *Dataset used/Linkage criteria of method/Number of cluster centers*.

To get a better idea of why gls/average/6 and gls/average/7 attain the ARIs they do, scatter plots of these two methods, and gls-EF/ward/2 have been given in figure 7.4. A scatter plot of the target variable patient diagnosis is also given for comparison. The dimensions used are peak systolic GLS in all three views as these are the dimensions that are common to all three methods. From the scatter plot in plot 7.10a one can see that the healthy patients are in the minority, and are concentrated in the corner with low peak systolic GLS values in the 4CH, 2CH and APLAX views. There are also some healthy patients with low-medium peak systolic GLS values, and very few healthy patients with high peak systolic GLS values. From plot 7.10b one can see that gls-EF/ward/2 is able to isolate the concentration of healthy patients with low peak systolic GLS, but at the cost of many FNs. \* In plot 7.10c and 7.10d one can see that cluster 1 of method qls/average/6, and cluster 2 of method qls/average/7 capture the healthy patients with low peak systolic GLS, but are unable of capturing the healthy patients with medium to high values. If one combines clusters 1 and 5 of gls/average/6, and lets them represent healthy patients, and let the remaining clusters represent unhealthy patients the method attains an accuracy of 0.74, a sensitivity of 0.70, a specificity of 0.94 and a DOR of 34.90. If one combines clusters 2 and 5 of gls/average/7, and lets them represent healthy patients, and let the remaining clusters represent unhealthy patients this method attains an accuracy of 0.74, a sensitivity of 0.70, a specificity of 0.94 and a DOR of 35.94. While the performance of the revised gls/average/6 and qls/average/6 methods are good, they are still not as good as the performance of the top three performers in terms of DOR, which attain higher accuracy, sensitivity and DORs. Therefore, rls-EF/complete/2 is chosen as the best of the PVC methods at identifying patient diagnosis, as it achieves the second highest DOR, and a more balanced sensitivity/specificity than qls-EF/ward/2 that attains the highest DOR score.

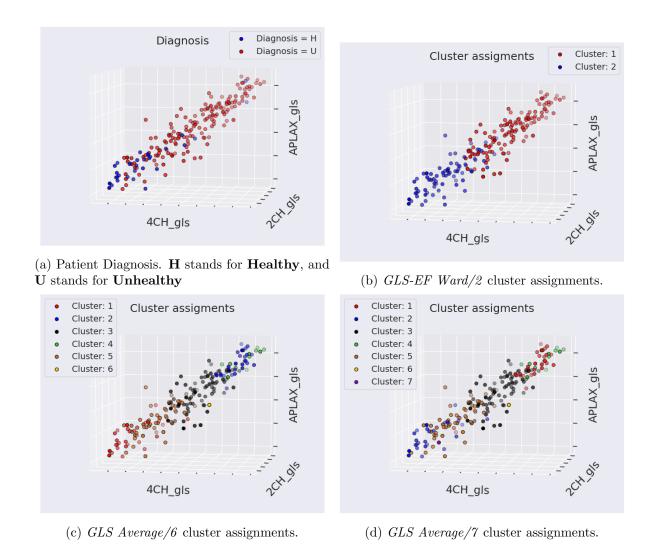

Figure 7.10: Scatterplot of peak GLS values in each view. Colors in the of the different dots are given by heart failure diagnosis, and cluster assignments of gls-EF/ward/2, average/6 and average/7 methods. Numbers are not included on the axes because the point of the figure is to illustrate the separability of clusters, and patient diagnosis.

Dataset-Model	Accuracy	Sensitivity	Specificity	DOR
all-strain/4CH/upsampled	0.83	0.99	0.00	0.00
all-strain/2CH/regular	0.85	1.00	0.00	NaN
gls/2CH/regular	0.85	1.00	0.00	NaN
rls/2CH/regular	0.85	1.00	0.00	NaN
all-strain/2CH/downsampled	0.85	1.00	0.00	NaN

Table 7.12: The accuracy, DOR, sensitivity and specicity scores of the five best performing variations of the NN in terms of DOR, when trained to predict patient diagnoses. The **Dataset-Model** column indicates Dataset used/View used/Whether curve has been upsampled, downsampled or is regular.

#### 7.2.3 Deep Neural Network

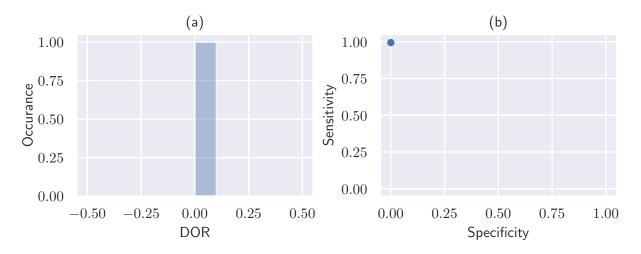

Figure 7.11: (a) Distribution plot of DOR of all NN models when trained to classify patient diagnosis. (b) Scatter plot of the same methods sensitivity, and specificity.

From the distribution plot in figure 7.11 one can see that the collective performance of the different variations of the NN trained to predict patient diagnosis is terrible. The DOR of all the methods are either zero because the number of TNs attained are zero, or not defined because the number of FNs are zero. The sensitivities are all 1, or close to 1, and the specificities are all 0. It is evident that the NNs are not able to generalize the traits of the healthy patients from such a small dataset. The NN models are will therefore not be discussed further with relation to prediction of patient diagnosis, and are not included in the comparison of the four model groups.

Dataset-Model	Accuracy	Sensitivity	Specificity	DOR
gls-rls-EF/Ada-Boost	0.95	0.97	0.79	138.42
${ m gls}{ m -rls}/{ m KNN}$	0.93	0.95	0.82	84.53
rls- $EF/Extra$ - $Trees$	0.93	0.96	0.75	76.50
gls-rls-EF/Extra-Trees	0.93	0.97	0.71	75.00
gls-rls/Extra-Trees	0.93	0.97	0.71	75.00

Table 7.13: The accuracy, DOR, sensitivity and specicity scores of the five best performing PVSC models in terms of DOR, when trained to predict patient diagnosis. The **Dataset-Model** column indicates *Dataset used/Specific machine learning model used*.

#### 7.2.4 Peak-value Classifiers

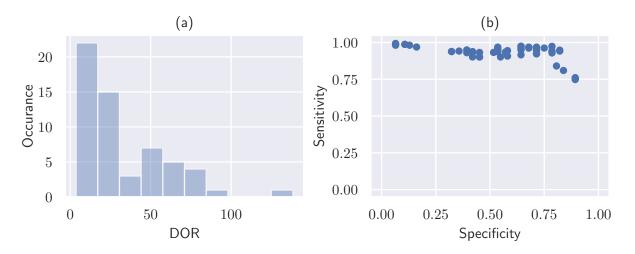

Figure 7.12: (a) Distribution plot of DOR of all PVSC models when trained to classify patient diagnosis. (b) Scatter plot of the same methods sensitivity, and specificity.

From the distribution plot in figure ?? it might seem like the majority of the DOR scores are close to zero, but in that is due to the shear spread of DOR scores so it should be said explicitly that the lowest DOR score of a PVSC model is 3.68 and is attained by the gls/Gaussian-Process model. The spread of DOR is so great that some models attain a DOR close to 100, and one method attains a DOR close to 150. From the scatter plot in figure ?? one can see that the sensitivity ranges from 0.75 to 1, and the specificity ranges from close to zero to approximately 0.95. Among the top five PVSC models in terms of DOR are many different combinations of models, and datasets. Three of the five highest DOR scores are attained by Extra-Trees models, and the top two scores are attained by KNN and Ada Boost classifiers. gls-rls-EF/Ada-Boost and gls-rls/KNN are the two top PVSC performers with regard to DOR. gls-rls-EF/Ada-Boost achieves the highest sensitivity of the two by two points, and gls-rls/KNN achieves the highest specificity of the two by three points. Since sensitivity and specificity is weighted equally in this study gls-rls/KNN is chosen as the best of the PVSC models trained to identify patient diagnoses.

Dataset-Model	Accuracy	Sensitivity	Specificity	DOR
TSC-gls/all-views/regular/weighted/2	0.82	0.81	0.83	21.06
$\mathbf{PVC}\text{-}\mathrm{rls}\text{-}\mathrm{EF/complete/2}$	0.77	0.74	0.93	37.61
$\mathbf{PVSC}$ -gls-rls/KNN	0.93	0.95	0.82	84.53
Dataset-Model	TP	TN	FP	FN
TSC-gls/all-views/regular/weighted/2	136	24	5	31
$\mathbf{PVC}\text{-}\mathrm{rls}\text{-}\mathrm{EF/complete/2}$	117	27	2	42
$\mathbf{PVSC} ext{-gls-rls/KNN}$	147	23	5	4

Table 7.14: A table comparing the best contenders within each model group for predicting patient diagnoses. The top table compare the models by their accuracy, sensitivity, specificity and DOR, and the bottom table shows the number of TPs, TNs, FPs and FNs that the different models attain on their respective datasets.

#### 7.2.5 Comparisons

From the top table in 7.14 one can see that there is a significant difference in performance between the three models included for comparison. The TSC model gls/all-views/regular/weighted/2 attains the second highest accuracy, sensitivity and specificity of the three models, but also attains the lowest DOR. The TSC model can also be said to attain the most balanced scores in terms of sensitivity and specificity. The PVC model rls-EF/complete/2 attains the highest specificity, second highest DOR, but lowest sensitivity and accuracy of the three models. The PVSC model gls-rls/KNN attains the highest accuracy, sensitivity and DOR of all the models, but it also achieves the lowest specificity of all the models. However, since the PVSC model is so close to the TSC model in terms of specificity, and is so much better than the other two models in all other metrics, it is chosen as the best model of identifying patient diagnoses. This can be confirmed from the bottom table in 7.14, where one can see that the PVSC model only gets one TN less than the TSC model, but attains 11 more TP.

#### 7.3 Case Study: Segment Indication

#### 7.3.1 Time-series Clustering

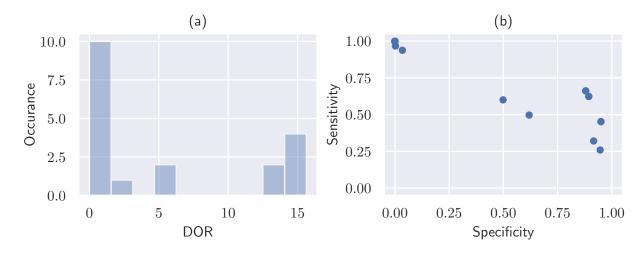

Figure 7.13: Distribution of DOR, sensitivity and specificity for the different TSC methods when classifying left ventrice segment indication.

Dataset-Method	Accuracy	Sensitivity	Specificity	DOR
regular/weighted/2	0.69	0.45	0.95	15.63
${\rm scaled/weighted/2}$	0.69	0.45	0.95	15.63
${\rm regular/ward/2}$	0.77	0.66	0.88	14.26
scaled/ward/2	0.77	0.66	0.88	14.26
${\rm regular/complete/2}$	0.75	0.62	0.89	13.92

Table 7.15: The accuracy, DOR, sensitivity and specicity scores of the five best performing twocluster-center TSC methods in terms of DOR, at detecting segment indication. The **Dataset-Method** column indicates *Type of preprocessing used/Linkage criteria of method/Number of* cluster centers.

From the distribution plot in figure 7.13a one can see that the majority of the DORs are close to zero, but a few methods are able to achieve DORs above 12, and some methods attain a DOR close to 15 when applied to identify segment indication. From the scatter plot in figure 7.13b one can see that the sensitivity of the TSC methods range from 0.25 to 1, and the specificity of the TSC methods range from 0 to approximately 1. The spread in both sensitivity and specificity is quite large, and there are very few methods that are able to a attain a high sensitivity while at the same time attaining a high specificity, and vice versa. Common to the high performing TSC methods in terms of DOR is that they all use either no preprocessing at all, or scaling. z-norm/complete/2 is the seventh best TSC method in terms of DOR, and attains a DOR of 5.92 when applied to identify segment indication. norm/ward/2 is the ninth best methods in terms of DOR, and attains a DOR of 1.56, when applied to identify segment indication. This can be comfirmed from table 10.3 The two TSC methods attaining the highest DORs regular/weighted/2, and scaled/weighted/2 differ only in type of preprocessing used. From table 7.15 and table 10.3 one can see that the two methods attain the same scores in all metrics, this is because they yield the exact same cluster assignments to the individual segment strain curves.

Dataset-Method	ARI
scaled/centroid/5	0.286
regular/centroid/5	0.286
regular/ward/2	0.284
scaled/ward/2	0.284
scaled/centroid/6	0.271

Table 7.16: The five highest ARI scores attained when applying TSC for detecting segmend indication. The **Dataset-Method** column indicates Type of preprocessing used/Linkage criteria of method/Number of cluster centers.

The same goes for the next two TSC methods in line regular/ward/2 scaled/ward/2, these two methods are also the methods that attain the highest accarcy of all the TSC methods. Of the two TSC methods regular/weighted/2, and regular/ward/2 the latter is preferred for predicting segment indication because regular/ward/2 has a more persistent performance in both sensitivity and specificity, where as regular/weighted/2 has a high specificity, but a very low sensitivity.

The majority of the ARIs of TSC methods applied to identify segment indication, but as one can see from table 7.16 some methods are able to attain ARIs above 25. As with the other case studies, the TSC methods that attain the highest ARIs are methods that use either no preprocessing at all or scaling. Puzzlingly enough the top two TSC methods for classifying segment indication in terms of ARI, are methods evaluated at five cluster centers, not two. TSC methods scaled/centroid/5, and regular/centroid/5 differ only in type of preprocessing used, and they yield the exact same cluster assignments, and evaluations scores. The next two methods in order of ARI regular/ward/2, and scaled/ward/2 are familiar from the list of TSC methods attaining the highest DORs when applied to identify segment indication. From table 7.16 one can also see that the difference in ARI between regular/centroid/5, and regular/ward/2 is only 0.002 Since the regular/ward/2 method will be considered the best of the TSC methods at classifying segment indication. It attains the third highest ARI of all the TSC methods applied to identify segment indication, and is the preferred method among the TSC methods evaluated at two cluster centers.

#### 7.3.2 Deep Neural Network

Method	Accuracy	Sensitivity	Specificity	DOR
regular	0.74	0.80	0.68	8.65
${\it downsampled}$	0.74	0.74	0.75	8.38
upsampled	0.65	0.55	0.73	3.36

Table 7.17: Evaluation metrics of the NN for classifying the binary indication of individual segments in the left ventricle.

Of the three variations of the NN model, the one that uses no resampling, and the one that downsamples all signals to the lowest sample rate achieve relatively similar DOR scores. The variation that upsamples the sample rate of all the curves to the highest sample rate performs significantly worse than the other two in terms of DOR and sensitivity. Of the three variations the model that uses downsampling is the preferred model of the three since its sensitivity and specificity are more balanced than the method that uses no resampling, and accuracy is higher than the method that uses upsampling.

#### 7.3.3 Comparisons

From table 7.18 one can see that the performances of the NN, and TSC models are quite close in terms of accuracy, but differ significantly in the other metrics. The TSC model regular/ward/2 attains a higher accuracy, specificity and DOR than the NN model downsampled. This can also be confirmed by the fact that the TSC model attains more TN, and fewer FP than the NN model. The NN model attains the highest sensitivity, which can be confirmed by the fact that it attains more TP and fewer FN than the TSC model. The NN model is also the model that attains the most balanced scores of sensitivity and specificity. Therefore the NN model is chosen as the best performer at predicting the segment indication.

Dataset-Model	Accuracy	Sensitivity	Specificity	DOR
TSC-regular/ward/2	0.76	0.64	0.88	13.15
${f NN} ext{-downsampled}$	0.74	0.74	0.75	8.38
Dataset-Model	TP	TN	FP	FN
TSC-regular/ward/2	1202	1491	204	616
${f NN}$ -downsampled	1255	1390	473	440

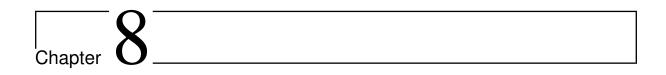

Table 7.18: A table comparing the best contenders within each model group for predicting segment indication. The top table compare the models by their accuracy, sensitivity, specificity and DOR, and the bottom table shows the number of TPs, TNs, FPs and FNs that the different models attain.

#### **Chapter Summary**

In the heart failure case study the PVC model was found to be the best performer, by a narrow margin. The TSC, and PVSC models also performed well, but the NN did not. In fact, the performance of the NN was not much better than what could be achieved by randomly guessing the binary label with equal probability of choosing one or zero. The PVC model that performed best at identifying heart failure among patients is gls-EF/complete/2, and it attains an accuracy of 0.76, sensitivity of 0.81, specificity of 0.72 and DOR of 10.85.

In the patient diagnosis case study the PVSC model is regarded as the top performer. Here too, it was a close call between the PVSC, PVC and TSC models. The patient diagnosis dataset was skewed as there were 170 patients with a heart disease, and only 30 healthy patients. For this reason it is probable that the NN was unable to generalize the feature of the healthy patients, because almost all the variations of the NN ended up always making the prediction that the patient was diseased yielding a score of 0 in specificity. The PVSC model that performed best at predicting patient diagnosis is gls-rls/KNN, and it attains an accuracy of 0.93, sensitivity of 0.95, specificity of 0.82 and DOR of 84.53.

In the segment indication case study only the TSC and NN models were compared, and for a change of pace it was only the NN that was chosen as the best performer. The TSC model did not perform much worse, in fact it performed better than the NN in many respects. The key reason for why the NN was preferred was because it had a more balanced sensitivity, and specificity scores than the TSC model. The NN model that performed best at predicting segment indication is *downsampled*, and it attains an accuracy of 0.74, sensitivity of 0.74, specificity of 0.72 and DOR of 8.38.

### Discussion

In the results chapter, the performance results were presented in the order of the different target variables that were explored. In the discussion chapter a different approach is taken, and the each model will be discussed individually based on their performance in the case studies.

#### 8.1 Time-series Clustering

- Give a brief summary of how the TSC model was implemented.
  - Before dissimilarity was measured between strain curves, curves were preprocessed in one of four ways.
  - Curves were either: not preprocessed, scaled between zero and one, normalized between zero and one or z-score normalized.
  - The TSC model was implemented by using DTW distance between strain curves as a dissimilarity measure to achieve a shape-based TSC model.
  - All the dissimilarity measures between a specific strain curve of one patient to the same strain curve of every other patient were combined into a dissimilarity matrix.
  - If the dataset represented patients with more than one strain curve the dissimilarity matrices of each indivial strain curves were added together, such that there was a single dissimilarity matrix that represented the dissimilarity between the patients.
  - The dissimilarity matrix was then passed to the hierarchical agglomorative clustering algorithm which started out with each patient as an indivial cluster, and merged clusters together based on a specific linkage criteria.
  - Seven linkage criteria were tested: single, complete, average, ward, centroid, median and weighted.
  - The clustering model was calculated at the different number of cluster centers between two and nine.
  - The ARI was estimated for the all the cluster assignments generated, and the different target variables.
  - For the cluster assignments yielded by a clustering model evaluated at two cluster centers the accuracy, sensitivity, specificated and DOR was also calculated.

#### • Mention briefly which placements TSC has in the different case studies.

 The TSC models did not perform best in any of the case studies, but variations of the TSC models generally yielded results with high performance in terms of accuracy, sensitivity and specicity.

- In the heart failure case study the best variation of the TSC model achieved the highest sensitivity and DOR, but it was outperformed by the best variation of the PVC model overall.
- In the patient diagnosis case study the best variation of the TSC model outperformed the best variation of the PVC model, but they were both outperformed by the best PVSC model.
- In the segment indication case study the best variation of the TSC model attains the highest accuracy, specicity and DOR, but is outperformed by the NN because it attains a higher sensitivity score, and thereby attains a more balanced accuracy in the positives and negatives.

#### • Discuss why methods using data from single view performed better.

- As discussed in section REFERENCE, a challenge for all statistical models is the "curse of dimensionality". Briefly described, in ML, and data mining the curse of dimensionality refers to the issue of attaining a good balance between the number of dimensions that an object is represented in, and the number of objects used to train and/or evaluate the model.
- In the heart failure and patient diagnoses case studies the TSC models that perform best in terms of DOR, and ARI are the models that use datasets where there are objects are represented by fewer dimensions.
- A reason for this could be that for 200 patients, the heart failure diagnoses, and patient diagnoses are most seperable for the TSC models when only one strain curve is used.
- The curve that then gives the easiest separation of patients is then the 2CH GLS curve.
- In the heart failure study the TSC models that attain the five best performing models in terms of DOR and ARI only use the GLS curve from the 2CH view, meaning that these methods only use one of 21 possible curves. This can be confirmed from table 7.1 and 7.2.
- In the patient diagnoses study one can see from table 7.8 that the five methods that attain the highest DOR also only use the GLS curve from the 2CH view.
- These two observations support the claim that at a dataset size of 200 objects using fewer strain curves makes it easier for TSC models to separate heart failure diagnoses, and patient diagnoses.
- An observation that does not directly support this claim is that in the patient diagnosis case study, the TSC models that attain the four highest ARI use a combination of GLS and RLS curves in the 4CH view, or use the GLS curves from all views.
- However, these methods also only use three and seven of 21 curves in total, so this observation does not negate the claim entirely.

### • Discuss why methods using data using "regular" or "scaled" performed better than methods using normalization or z-normalization.

- In all case studies it was found that TSC models that performed best in terms of DOR, and ARI used no preprocessing.
- In some cases models using scaling as a form of preprocessing yielded the same cluster assignments, which could indicate that scaling the curves before measuring dissimilarity does not make much of a difference.

Since TSC models using normalization or z-score normalization as a form of preprocessing were not among the top five methods in terms of DOR, or ARI in any of the case studies the argument could be made that these form of preprocessing are not suited when using DTW as a dissimilarity on left ventrice strain curves.

#### • Talk about the performance of different linkages.

- Of the seven linkages tested, it was the centroid, weighted and ward linkages that went into the TSC models that performed best at predicting heart failure, patient diagnosis and segment indication respectively, in the different case studies.
- However, the single, complete and average linkages also went into the methods that appeared in the top five candidates in terms of DOR, or ARI.
- So it is not possible to say certainly that all linkages other than centroid, weighted and ward linkages are not suited for clustering left ventricle strain curves, but one can say with some degree of certainty that the median linkage does not go into any of the TSC models that perform well in any of the three case studies.

#### • Talk about run-time challenges.

- When calculating the dissimilarity matrix of a set of 200 curves, it took approximately
   0.3 seconds using the C-optimized functions of the dtaidistance library.
- The time it took to compute the clustering varied between 0.15 and 0.45 seconds depending on what linkage was used.
- The single linkage criteria was found to be the fastest, and the complete linkage was found to be the slowest.
- That the single linkage was the fastest could is to be expected, as it fairly easy to compute.
- However, it was unexpected that the complete linkage was the one that took the longest time to compute as one would expect the more complex linkages such as the ward linkage to take the longest time to compute.
- When the size of the dataset was increased to approximately 3600 curves it took 162 seconds to compute the dissimilarity matrix.
- This increase in run time is in agreement with the time complexity of the DTW algorithm described in section REFERENCE.
- In addition, the time it took to compute the clustering after the dissimilarity matrix was computed also increased to vary between 3 seconds for the single linkage, and 871 seconds for the ward linkage.
- So for a bigger dataset the run time of the different linkages were more as expected.
- Although these run-times are attained with a with a regular desktop Lenove G510 laptop, it illustrates possible challenge of how run-time of the calculations of the dissimilarity matrix, and clustering increase quadratically with the size of the dataset.

#### • Improvements that could be done on the existing model

- It was often found that the PVC models that used EF in addition to peak systolic strain values performed better than the PVC models that only used strain values.
- It would be interesting to see whether incorporating EF in the TSC model would improve its performance as well.

- Since the hierarchical agglomorative clustering algorithm is uses dissimilarity matrix to cluster objects, it should be fairly straight-forward to calculate the dissimilarity matrix between a patients EF values, and add that to the dissimilarity matrices of the indivial curves.
- However, it falls outside the scope of this thesis.

#### 8.2 Peak-value Clustering

- Give a brief summary of how the PVC model was implemented.
  - The PVC model was implemented in a similar fashion as the TSC model.
  - The datapoints used to represent patients were passed to an implementation of hierarchical agglomorative clustering in scikit-learn.
  - The dissimilarity between patients was measured as the Euclidean distance between the dimensions used to represent them.
  - The scikit-learn implementation did not have all the same clustering linkages available as the scipy implementation used for TSC, so only the following four linkages were tested: single, complete, average and ward.
  - The evaluation procedure for the PVC model was the same as the procedure used for TSC.

#### • Mention briefly which placements PVC has in the different case studies.

- The best variations of the PVC model had a high performance in the heart failure, and in the patient diagnosis case studies.
- It was chosen as the best model in the heart failure case study, but was closely followed by the TSC, and PVSC models.
- In the patient diagnosis case study the best variation of the PVC models attained the highest specifity, and second highest DOR of the three models compared.
- However, it was outperformed by both the TSC, and PVSC models due to its low sensitivity.

# • Note that the PVC methods that use combination of peak systolic strain values and EF performs significantly better, future work could be to combine EF values with strain curves as well.

- In both case studies PVC models that used datasets that were a combination of peak systolic strain values and EF performed consistently better than the models than only used the strain values.
- This is to some degree expected in the heart failure case study, as EF is parameter that is established in the current medical procedures used to diagnose patients with heart failure.

#### • Talk about the performance of different linkages.

- In the heart failure case study it was the complete linkage which was used in the model that was chosen as the best performer, but the ward, and average linkages were also used in the models that attained the top five DOR and ARI scores.
- In the patient diagnosis case study the complete linkages was also used in the model that was chosen as the best performer.

- In both case studies where PVC models where tested the models that were chosen as the best performers used the complete linkage, but the average and ward linkages were also used by other model variations that attained the five highest DOR and ARI.
- Hence, for PVC models using peak systolic strain values, and EF to identify heart failure among patients, and patient diagnosis the single linkage was not found to be suited.

#### • Talk about run-time challenges.

- Since a scikit learn implementation was used for the PVC model, it was not possible to separate run-time of the dissimilarity calculation and the clustering itself.
- However, Euclidean distance is known to scale linearly with the number of dimensions per object, and number of objects in the dataset.
- Since the underlying algorithm used by scikit learn is the same as the one used by scipy it is assumed that it would perform similarly to the TSC model in terms of run time.

#### 8.3 Neural Networks

#### • Give a brief summary of how the NN model was implemented.

- For the NN two types of preprocessing were tested in addition the option of not preprocessing at all, upsampling the curves to the highest sample rate in the dataset and downsampling the curves to the lowest sample rate.
- The curves of the dataset were then passed as input to the NN architecture detailed in section REFERENCE together with the relevant target variables.
- The NN was trained for five epochs using the backpropagation algorithm and SGD.
- To validate the NN models 10-fold cross validation was used, at the end of each fold the TP, TN, FP, and FN of the model were noted.
- After the NN had effectively attempted to predict every object of the dataset all the TP, TN, FP, and FN were summed and this grand total was used to estimate the models accuracy, sensitivity, specicity and DOR.

#### • Mention briefly which placements NN has in the different case studies.

- The NN models performed worst of the four model groups in the heart failure case study, and the patient diagnosis case study.
- However, it attained the highest sensitivity in the segment indication case study, and was chosen as the best performing model because its sensitivity and specicity were more balanced than the TSC model.

#### • Talk about performance of NN in different case studies.

- In the patient diagnosis case study close to all of the NN models predicted all the patients to be unhealthy.
- It is evident that a NN with the architecture used in this assignment was not suited to classify patient diagnosies with a skewed dataset of only 170 unhealthy patients and 30 healthy patients.

- It is the authors opinion that the reason that the NN models performed so bad at predicting patient diagnosis is an aspect of "the curse of dimensionality", and that the network was not able to generalize the characteristics of healthy patients in the study, and therefore minimized loss function by predicting the outcome that was most probable.
- From table 10.6 one can see that the top nine variations of the NN model that performed best in the heart failure case study with regard to DOR, were models that used only the GLS curve from a single view, which supports the claim that
- Since the different NN models differed in architecture depending on how many curves were used to represent one patient, they also varied in the number of trainable parameters they have.
- The NN models which only take a single strain curve as input have 39457 trainable parameters, and the NN models that take 21 curves as input have 80417 trainable parameters.
- Even though there is no exact ratio of how big a dataset should be with regard to how many trainable parameters a model has, between 40 and 80 thousand parameters for a dataset of size 200 is likely too many trainable parameters.
- On the other hand, the NN model was chosen as the best performing model at predicting segment indication.
- In that case study though the size of the dataset is significantly larger, and each object is represented by a single curve.
- Considering that the architecture of the NN was given, and not developed specifically
  for this classification problem the performance that the model achieves is significant.

#### • Possible improvements

- It is the authors opinion that if more time is spent adapting the model to the dataset at hand, even better performances are within reach.
- Especially for the segment indication classification problem where there is so much data, there is potential.
- There are alternatives to SGD that could be tested such as batch gradient descent, and the most popular choice mini-batch gradient descent which is a middle road between the two, and is often considered the best alternative REFERENCE.
- There is also the GRU cells that are an alternative to the LSTM cells. Like LSTM cells, GRU cells are able capture time-dependent connections. GRU cells are simpler than LSTM cells in composition, and are said to require less training data, to achieve the same accuracies as LSTM cells REFERENCE.
- It could also be considered whether it would be beneficial to use some form of dimensionality reduction such as a max pooling layers, which for time series can be considered as a max-filter where only the highest value in a segment of a curve is kept on.
- Dropout layers are also a technique that are used frequently when NN architecture become deep and complex, they introduce the probability that any particular perceptron in the layers preceding the dropout layer can "drop out" meaning that they become inactive.
- In complex NN architectures it is often found that during training the model becomes overly dependent on certain perceptrons, and specific paths through the network. This leads to the NN not entirely utilizing all the perceptrons at its disposal, and the accuracy suffers. It is found that by adding a probability that any given neuron can drop out during training remedies this effect, and can increase accuracy overall.

#### • Talk about run-time challenges.

- Training, and validating the NN models were one of the more time-consuming computations required.
- The time it took to train the network depended on what dataset was used, which makes sense as increasing the number of curves the NN can take as input also increases the number of trainable parameters that need to be trained for each step of the SCG algorithm.
- When validating the NN models, a single fold in the 10-fold cross validation took approximately 100 seconds in the heart failure, and patient diagnosis case studies.
- The time it took to execute one fold in the segment indication case study took approximately 640 seconds (11 min)
- However, these times do not reflect the times it will take to use the NN to evaluate new cases after training, so the same challenge one has with clustering is not as pressing should the aim be to deploy the NN in a real-time clinical setting.

#### 8.4 Peak-value Supervised Classifiers

#### • Give a brief summary of how the PVSC model was implemented.

- The different peak-value datasets are passed the different supervised classifiers in the model group.
- The different datasets are detailed in section 6.2, and the different supervised classifiers tested are detailed in section REFERENCE.
- Each combination of dataset and classifiers is validated by a 10-fold cross-validation in the same manner as the NN.

#### • Mention briefly which placements PVSC has in the different case studies.

- In the heart failure case study the best PVSC model outperformed the best variations of the TSC, and NN models and had a performance that was on par with the PVC, although the best PVC model was ultimately deemed better in the end.
- In the patient diagnosis case study the best PVSC model attained the highest accuracy, sensitivity and DOR of the four model groups, and it was deemed the best model group at predict patient diagnosis.

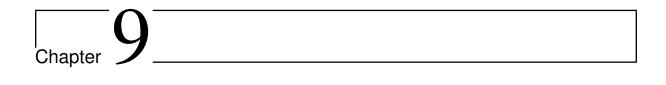

## • Mention that DOR distribution of PVSC models were significantly higher centered than the other models groups DOR distribution.

- What should be addressed is the fact that the distribution of the DOR for the different PVSC models, differ from the DOR distributions of the other models in some key ways.
- In both the heart failure case study, and the patient diagnosis case study the distribution of DOR for variations of TSC, PVC and NN models are highly concentrated around zero.
- For the PVSC models the lowest DOR attained by a PVSC model in the heart failure study is 1.94, and the lowest DOR attained by a PVSC model in the patient diagnosis case study is 3.68.
- In the heart failure case study it is especially evident that the DOR of the different PVSC models is distributed differently than the DOR of the other models.

- It can be confirmed from figure ?? that the distribution of DOR for the PVSC is especially concentrated in the range between four to eight.
- The significance of this difference of DOR distribution is two-fold, the first thing to keep in mind is that not very much time was spent optimizing the hyperparameters of the PVSC models as it falls outside the scope of this thesis, and that in contrast to the clustering models the outcome of the PVSC model is probabilistic in the sense that it is highly dependent on the initial conditions of the model before it is trained.
- Since the DOR distribution of PVSC models in the heart failure, and patient diagnosis case studies are distributed higher in general than the TSC and PVC models, and that the PVSC are configured with what can be considered as "standard hyperparameters" it is probable that spending time on optimizing the hyperparameters of the PVSC models, and testing different initial conditions could improve the performance of all the PVSC models.

#### • Talk about run-time challenges.

- The time it took to train and validate the PVSC models varied, and was highly dependent on the dimensions of the dataset and which specific ML model was used.
- The shortest training time encountered was at 201 seconds, and the longest was at 365 seconds.

# Conclusion

This is the conclusion.
